

# IPv4 Distribution Options for the Last Eights

Choice of Risks and Assumptions

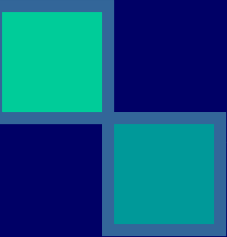

# Previous Observations about Adoption

- What is a reasonable, available measure?
  - Can the diffusion uncertainty be bound and quantified?
  - Is there a feasible path which results in short IPv4/IPv6 co-existence?
  - What are the implications in terms of possible actions?
- 

# Previous Findings

- 
- What is a reasonable, available measure?
    - Routes and ASNs yield similar near-term results
    - The diffusion uncertainty was bound and quantified given this data.
  - There is no feasible path which results is less than years of IPv4/IPv6 co-existence. Decades is not unreasonable.
  - Observations from economics of security applied to IPv6; implications are that normal market measures may not result in diffusion.
- 

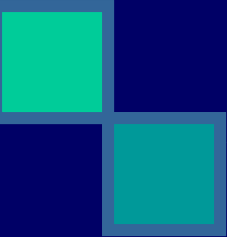

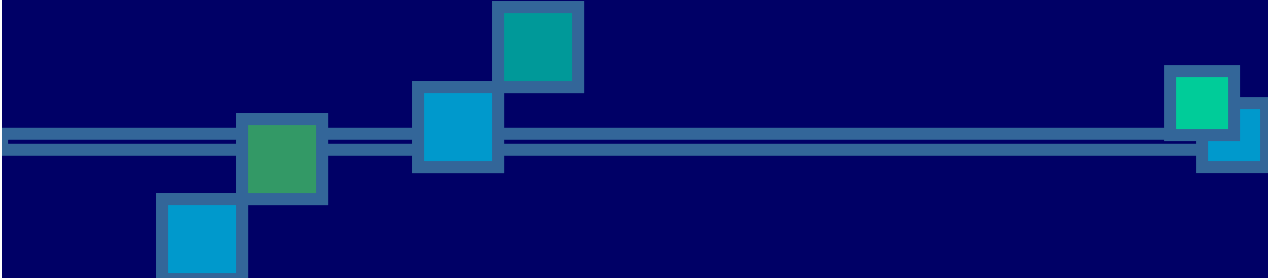

# Options

- Do Nothing
  - Government leads
    - This has been tried ...
  - RIR Lead: Market
  - RIR Lead: Other
- 

## RIR Lead: Other

- 
- Only allocate to organizations with a small address space previously allocated
  - Only allocate a given amount of the v4 space per year
  - Provide only a minimal routable allocations per organization per year
- 

# Policy Requirements (Potaroo)

- Address policies are intended to be applied uniformly
  - Addresses are made available from the unallocated pool to meet demands for their use in networks
  - The prevailing address policy regime characterizes addresses as a network attribute
- 

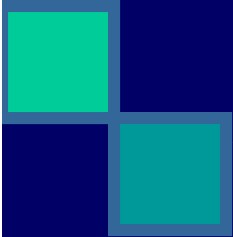

# Not Policy Requirements

- Market requirements: Strong convexity requirement
    - $16 * \text{Price} (/24) < \text{Price}(/20)$  in all cases
    - This fails if IPv4 becomes a gateway technology or critical facility
  - Avoidance of destructive market behaviors
    - speculation
- 

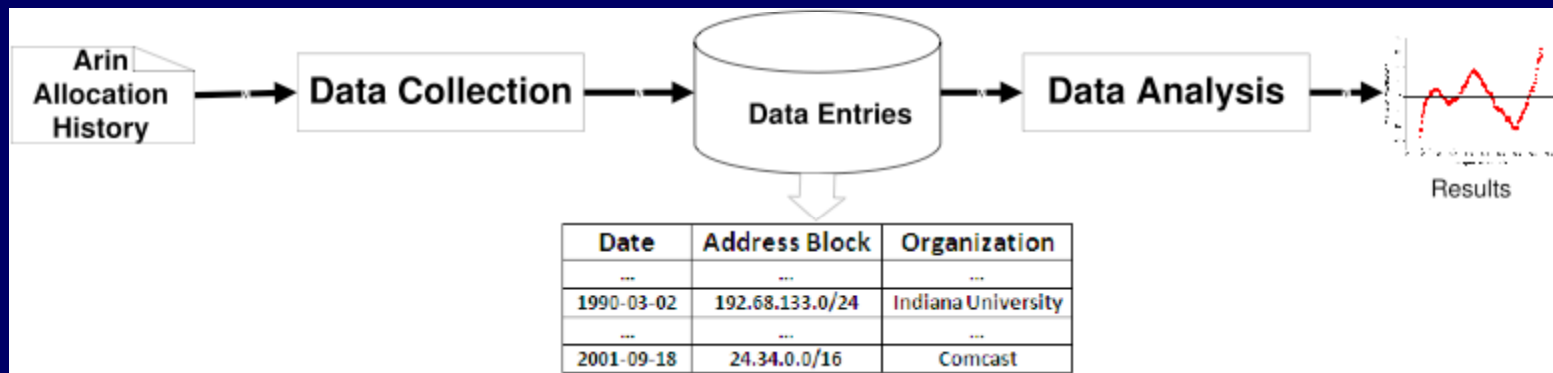

# Data and Assumptions

- 
- Consistency over time
  - IANA splits remaining blocks equally
  - Whois is roughly correct
- 

# Data Foundation

- Regional Internet Registry (RIR) stats file
  - IPv4 address allocation history of ARIN.
- ARIN Whois and Cymru Whois
  - Associate AS to IPv4

# Data Modeling Trends

# Data Modeling Result

Allocation Range	Organizations in Range	Equivalent in /16s
/8 block $\leq$ Allocation	34	395 /16s
/12 block $\leq$ Allocation < /8 block	103	49 /16s
/16 block $\leq$ Allocation < /12 block	1268	712 /24s
/20 block $\leq$ Allocation < /16 block	3207	48 /24s
/24 block $\leq$ Allocation < /20 block	4302	5 /24s
Allocation < /24 block	8202	1 /24s

# Policy 1: Organization Threshold

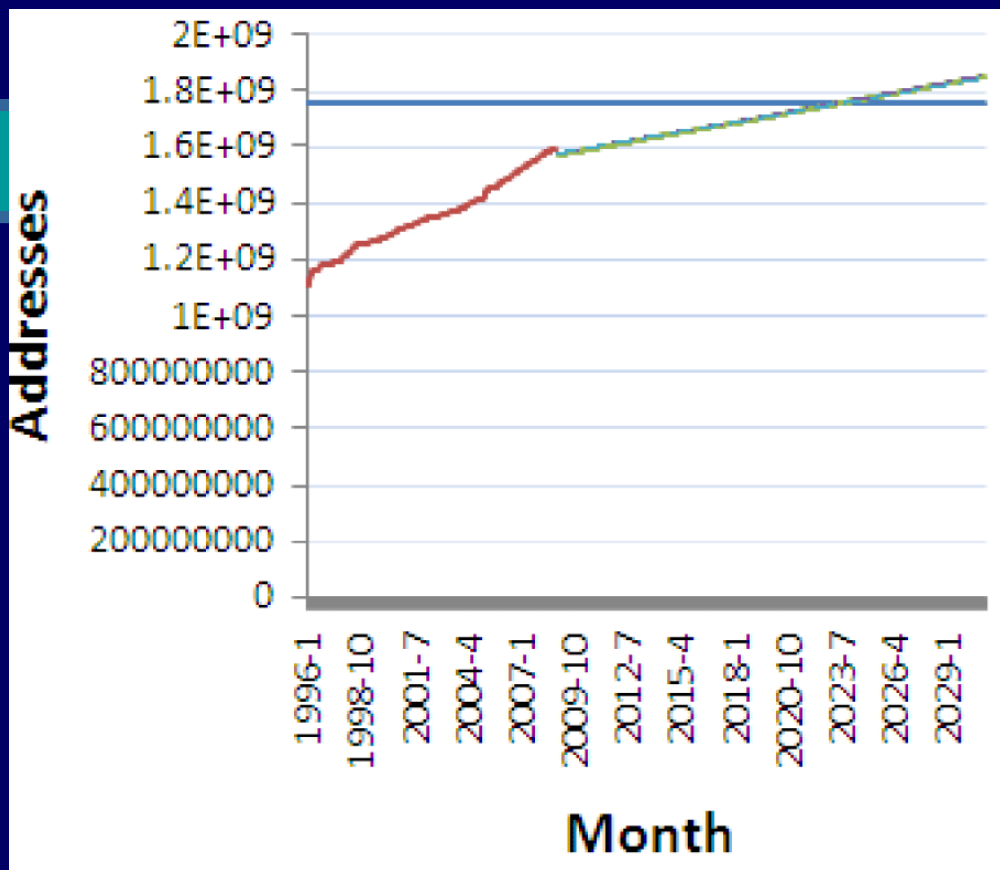

- Organizations above a certain threshold receive no additional addresses
  - Justification
    - Larger organizations have tended to request large additional block
    - Larger organizations have more aggregate networking expertise to move to v6
    - Experience in translation at large scale could hasten v6 adoption, mitigating uncertainty for all parties
    - Capacity, motivation, and impact
- 

# Modeling

- Subtract residual addresses from historical data.
  - Use this data to form a projection, calculating linear and polynomial fits.
  - Add the residual addresses back into projection for a starting or initial point for the projection.
  - Use the curve generated to project exhaustion.
    - Imagine this policy had always been in place
    - Use this imagine the implications of the policy for the future
    - Begin 1997
- 

# Implications

- Using /12 as a threshold, a crossover in 2024 (or 2019)

# Implications

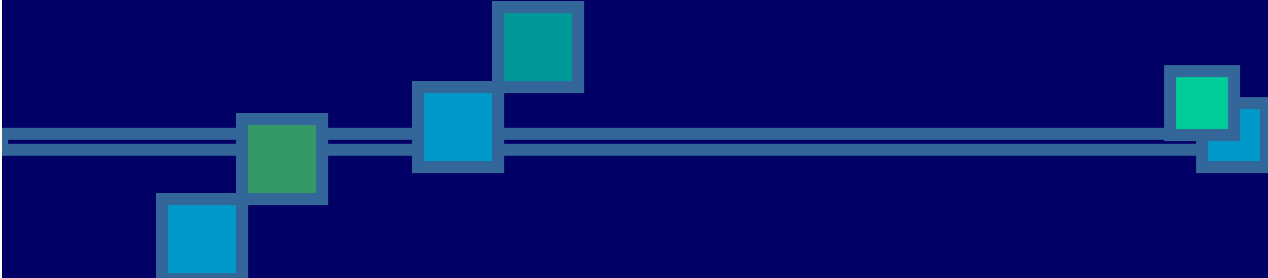

- Using /20 as a threshold, exhaustion approaches 2045

# Summary of Policy 1 Simulations

Model	Threshold/12			Threshold/16			Threshold/20		
		-\%95 PI	+\%95 PI	Projected	-\%95 PI	+\%95 PI		-\%95 PI	+\%95 PI
Linear	1/2024	11/2023	4/2024	12/ 2041	7/2040	8/2043	12/2060	8/2056	4/2066
Polynomial	3/2019	3/2019	3/2019	6/2029	5/2029	7/2029	12/2045	11/2045	2/2046

- Assuming yesterday predicts tomorrow....

## Policy 2: Per organization annual threshold

- Provide any organization that requests an allocation exactly one minimal routable block
  - Justification
    - Fairness
    - Politics
- 

# Past Organizational Patterns

# Resulting Per Organization Results

- Multiply number of organizations times allocations
  - Select allocation size as minimally routable
    - /24?
  - Determine exhaustion date by organizational count
- 

# Results for Policy 2

Results with a /18 and /20 as maximum allocations

## Results for Policy 2

Allocation Size	/22	/20	/18
Estimated exhaustion	2060	2030	2017

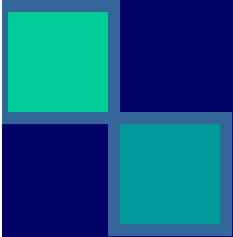

## Policy 3: Predetermine Exhaustion

- More of a thought experiment
  - Pick a year
  - Divide pool by time to that year
  - Allocate pool at a rate to make it to that year
- 

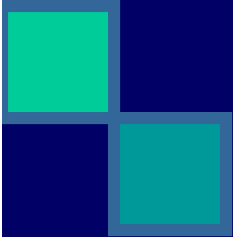

# How Low Could You Go?

- 
- How small an allocation can you place in any given year before the allocations become impossible to route?
  - How many allocations are you getting, per year, per average?
  - Who would be refused?
  - You can make this decision later than others.
- 

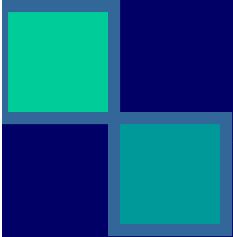

## As Low as You Like

- 
- $3 / 8 = \sim 200k / 24s$
  - 2000 24/s per year the result is 98 years
  - 30 years the meet requests of 95\% of applicants could in theory, be met.
  - 50 years the meet requests of 75\% of organizations could in theory, be met.
- 

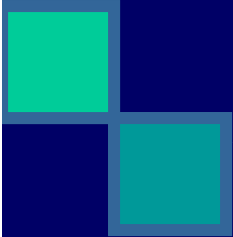

# It is Up To You..... For Now

- 
- RIR decisions could choose to manage exhaustion multiple ways
  - This will determine the transition
  - IPv4 will become in the next years
    - A critical facility?
    - A traded good?
    - A high level interconnection, backbone technology?
-
